

E-HealthCare Management

System flow & pipeline reference

JavaFX · JDBC · MySQL (XAMPP)

Contents

1. The pipeline
2. Patient flow
3. Doctor flow
4. Bed management
5. Illness classification
6. Status state model
7. Doctor queue & consultation
8. Hospital transfer
9. Patient file

1. The pipeline

How data flows: three roles to JavaFX to JDBC to MySQL and back.

New in this version: hospital admin is a third role, the transfers table is added, and transfer, admin inbox, and patient file are new screens. Everything else carries over from the original plan.

2. Patient flow

A patient's path from opening the app to receiving a prescription.

3. Doctor flow

A doctor's path from login to issuing prescriptions.

4. Bed management

How a bed is checked, assigned, and released on discharge.

5. Illness classification

Symptoms classified into categories, matched to a specialty.

6. Status state model

The statuses a patient and a doctor move through.

When doctor goes ON_HOLD: pending patients re-queue to another free doctor of the same specialty — if none exists, they stay pending for this doctor until they resume.

7. Doctor queue & consultation

Accept, consult, branch on severity, then next patient or hold.

8. Hospital transfer

Doctor refers a patient; admin reviews, requests the file, and confirms.

9. Patient file

The clinical record, opened by the doctor or shared with a hospital.
